Example Question: Explain the process of photosynthesis.

Sample Answer:

Introduction

Photosynthesis is the biological process by which green plants, algae, and some bacteria convert light energy into chemical energy stored in glucose molecules. This process is vital for life on Earth as it provides oxygen and sustains the food chain.

Main Body

The process occurs primarily in the chloroplasts of plant cells, utilizing chlorophyll to capture light energy. It consists of two main stages:

1. Light-Dependent Reactions: These occur in the thylakoid membranes, where sunlight excites chlorophyll molecules, leading to the splitting of water molecules (photolysis). This releases oxygen, protons, and electrons. The energy generated is stored in ATP and NADPH molecules.

2. The Calvin Cycle (Light-Independent Reactions): Taking place in the stroma, this cycle uses ATP and NADPH to convert carbon dioxide into glucose through a series of enzyme-driven steps.

Supporting Evidence & Examples:

- The overall simplified chemical equation of photosynthesis:

- **Example:** During the day, plants absorb sunlight, facilitating the photosynthesis process that produces oxygen and glucose vital for their growth.

Conclusion

In summary, photosynthesis is a complex yet essential process that transforms light energy into chemical energy, supporting life on Earth. Understanding this process highlights the importance of plants in maintaining ecological balance.
